

1.5 Amp Output Current IGBT Gate Driver Optocoupler

with Integrated (V_{CE}) Desaturation Detection, UVLO Fault Status Feedback, Active Miller Clamp and Auto-Fault Reset

Description

The SJS-330J is an advanced 1.5 A output current, easy-to-use, intelligent gate driver which makes IGBT V_{CE} fault protection compact, affordable, and easy-to implement. Features such as integrated V_{CE} detection, under voltage lockout (UVLO), "soft" IGBT turn-off, isolated open collector fault feedback and active Miller clamping provide maximum design flexibility and circuit protection.

The SJS-330J contains a LED. The LED is optically coupled to an integrated circuit with a power output stage. SJS-330J is ideally suited for driving power IGBTs and MOSFETs used in motor control inverter applications. The voltage and current supplied by these optocouplers make them ideally suited for directly driving IGBTs with ratings up to 1200 V and 100 A. For IGBTs with higher ratings, the SJS-330J can be used to drive a discrete power stage which drives the IGBT gate.

The SJS-330J has an insulation voltage of V_{IORM} = 1414 V_{PEAK} .

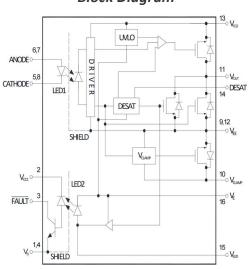

Features

- 1.5 A maximum peak output current
- 1.0 A minimum peak output current
- 250 ns maximum propagation delay over temperature range
- 1.0A Active Miller Clamp. Clamp pin short to VEE if not in used
- Miller Clamping
- Desaturation Detection
- Under Voltage Lock-Out Protection (UVLO) with Hysteresis
- "Soft" IGBT Turn-off
- Automatic Fault Reset after fixed Mute Time, typically 26 μs
- Available in SO-16 package
- 100 ns maximum pulse width distortion (PWD)
- 50 kV/ μ s minimum common mode rejection (CMR) at $V_{CM} = 1500 \text{ V}$
- I_{CC} (max) < 5 mA maximum supply current
- Wide V_{cc} operating range: 15 V to 30 V over temperature range
- Wide operating temperature range: -40°C to 110°C

Applications

- Isolated IGBT/Power MOSFET gate drive
- AC and brushless DC motor drives
- Industrial inverters and Uninterruptible Power Supply (UPS)

Notes:

- 1. Derate linearly above 70°C free air temperature at a rate of 0.3 mA/°C.
- 2. In order to achieve the absolute maximum power dissipation specified, pins 4, 9, and 10 require ground plane connections and may require airflow. See the Thermal Model section in the application notes at the end of this data sheet for details on how to estimate junction temperature and power dissipation. In most cases the absolute maximum output IC junction temperature is the limiting factor. The actual power dissipation achievable will depend on the application environment (PCB Layout, air flow, part placement, etc.). See the Recommended PCB Layout section in the application notes for layout considerations. Output IC power dissipation is derated linearly at 10 mW/°C above 90°C. Input IC power dissipation does not require derating.
- 3. Maximum pulse width = $10 \mu s$. This value is intended to allow for component tolerances for designs with IO peak minimum = 1.0 A. Derate linearly from 2.0 A at $+25 ^{\circ}C$ to 1.5 A at $+105 ^{\circ}C$. This compensates for increased I_{OPEAK} due to changes in V_{OL} over temperature.
- 4. This supply is optional. Required only when negative gate drive is implemented.
- 5. Maximum pulse width = $50 \mu s$.
- 6. See the Slow IGBT Gate Discharge During Fault Condition section in the applications notes at the end of this data sheet for further details.

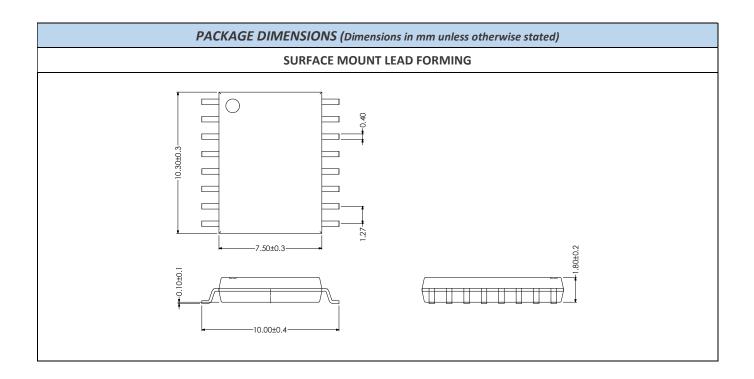

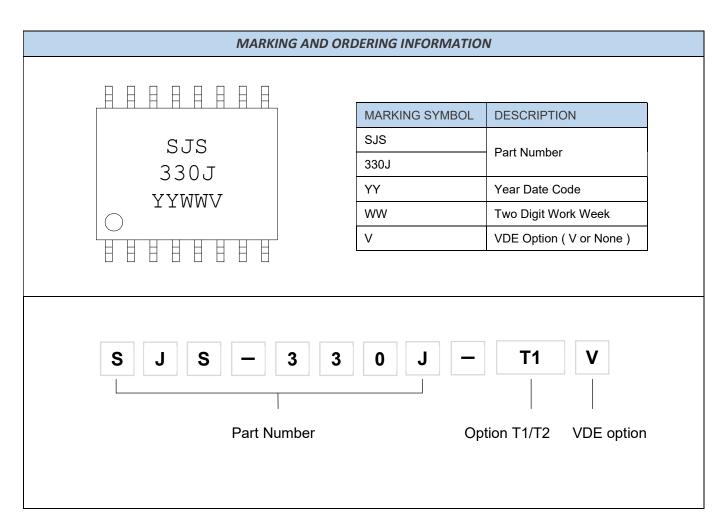

- 7. 15 V is the recommended minimum operating positive supply voltage (V_{CC2} V_E) to ensure adequate margin in excess of the maximum V_{UVLO+} threshold of 12.5 V. For High Level Output Voltage testing, V_{OH} is measured with a dc load current. When driving capacitive loads, V_{OH} will approach V_{CC} as I_{OH} approaches zero units.
- 8. Maximum pulse width = 1.0 ms.
- 9. Once VO of the SJS-330J is allowed to go high (V_{CC2} V_E > V_{UVLO+}), the DESAT detection feature of the SJS-330J will be the primary source of IGBT protection. UVLO is needed to ensure DESAT is functional. Once V_{CC2} is increased from 0V to above V_{UVLO+}, DESAT will remain functional until V_{CC2} is decreased below V_{UVLO-}. Thus, the DESAT detection and UVLO features of the SJS-330J work in conjunction to ensure constant IGBT protection.
- 10. See the DESAT fault detection blanking time section in the applications notes at the end of this data sheet for further details.
- 11. This is the "increasing" (i.e. turn-on or "positive going" direction) of $V_{CC2} V_E$
- 12. This is the "decreasing" (i.e. turn-off or "negative going" direction) of VCC2 VE
- 13. This load condition approximates the gate load of a 1200 V/75A IGBT.
- 14. Pulse Width Distortion (PWD) is defined as | tphl tplh | for any given unit.
- 15. As measured from I_F to V_O .
- 16. The difference between tphL and tplH between any two SJS-330J parts under the same test conditions.
- 17. As measured from ANODE, CATHODE of LED to V_{OUT}
- 18. This is the amount of time from when the DESAT threshold is exceeded, until the FAULT output goes low.
- 19. This is the amount of time the DESAT threshold must be exceeded before V_{OUT} begins to go low, and the FAULT output to go low. This is supply voltage dependent.
- 20. Auto Reset: This is the amount of time when V_{OUT} will be asserted low after DESAT threshold is exceeded. See the Description of Operation (Auto Reset) topic in the application information section.
- 21. Common mode transient immunity in the high state is the maximum tolerable dV_{CM}/dt of the common mode pulse, V_{CM} , to assure that the output will remain in the high state (i.e., $V_O > 15$ V or FAULT > 2 V).
- 22. Common mode transient immunity in the low state is the maximum tolerable dV_{CM}/dt of the common mode pulse, V_{CM} , to assure that the output will remain in a low state (i.e., $V_0 < 1.0 \text{ V}$ or FAULT < 0.8 V).
- 23. To clamp the output voltage at V_{CC} 3 V_{BE} , a pull-down resistor between the output and V_{EE} is recommended to sink a static current of 650 μ A while the output is high. See the Output Pull-Down Resistor section in the application notes at the end of this data sheet if an output pull-down resistor is not used.
- 24. In accordance with UL 1577, each optocoupler is proof tested by applying an insulation test voltage ≥ 6000 Vrms for 1 second. This test is performed before the 100% production test for partial discharge (method b) shown in IEC/EN/DIN EN 60747-5-5 Insulation Characteristic Table.
- 25. This is a two-terminal measurement: pins 1-8 are shorted together and pins 9-16 are shorted together.
- 26. Split resistors network with a ratio of 1:1 is needed at input LED1. See Figure 31.

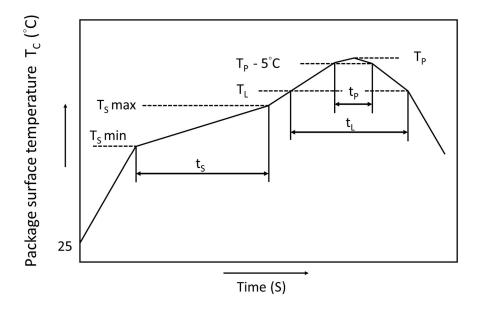

PRECAUTIONS FOR SOLDERING

IR Reflow soldering

One time soldering reflow is recommended within the condition of temperature and time profile shown below. Do not solder more than three times.

DESCRIPTION	SYMBOL	MIN.	MAX.	UNIT
Preheat temperature	Ts	150	200	°C
Preheat time	ts	60	120	S
